**Results so far**

**Donors**

Common tansy is an aromatic Eurasian plant species with a long history of use as a medicinal herb. Introduced for this purpose to North America, it has since become invasive. One reason for this could be the absence of the natural enemies that keep it in check in its area of origin. CABI has been tasked with identifying and releasing natural enemies to control its spread. In the US, it has been identified as a pest in several states, including Montana. In Montana, it is a noxious weed and is being targeted for control. CABI is working with Montana State University and other partners to identify and release natural enemies to control its spread. The project is ongoing and has resulted in the identification of several potential natural enemies. The project is funded by the Montana Noxious Weed Trust Fund through Montana State University, USA.
